Using Sandwich Composite Shells for Fully Pressurized Tanks on Liquefied Petroleum Gas Carriers

Veyesel Alankaya1,* – Fuat Alarçin2

1Turkish Naval Academy, Department of Naval Architecture, Turkey
2Yıldız Technical University, Department of Marine Engineering Operation, Turkey

The growth of shipping as the main link of the seaborne gas supply chain results from the growing demand for liquefied petroleum gasses due to their various uses, such as fuel for cooking/heating, automotive power, and numerous applications. This study investigates the structural suitability of sandwich composite materials for pressurized tanks, which can be used in on-board carriers or barges for transportation, as well as inland for industrial or residential storage needs. The analytical solution methodology for analysing stresses and deformations is based on higher order shear deformation theory (HSDT). A boundary discontinuous generalized double Fourier series approach is used to solve highly coupled linear partial differential equations. The complementary boundary constraints are introduced through boundary discontinuities, generated by the selected boundary conditions for the derivation of the complementary solution. Numerical solutions are presented for laminated sandwich shells having both cylindrical and spherical forms, which are the preferred geometries for pressurized tanks.

Keywords: sandwich composites, pressurized tanks, boundary-discontinuity, doubly curved shell, liquefied petroleum gas carriers

Highlights
- HSDT with arbitrary boundary conditions was studied.
- Laminated sandwich composite shells are analysed with the presented mathematical model.
- Results are in good agreement with FEA counterparts.
- Effect of core layer and geometry using stress distribution is presented.

0 INTRODUCTION

Petroleum gases, an alternative to fuel oil with lower prices, are preferred for numerous uses, which can be briefly listed as (i) in-house basic needs, such as cooking and heating, (ii) industrial needs for power plants, plastic and chemical applications, and (iii) propulsion fuel for transportation. This large operational suitability causes the configuration of a distribution network depending on pipelines for the areas with infrastructure, storages for field usage, or shipping solutions for seaborne supply.

The U.S. Energy Administration estimates energy consumption, which was approximately 825 million barrels in 2013, to increase by 0.6 % annually from 2012 to 2040 while the natural oil resources are declining [1].

Since many world oil resources are difficult to reach, growth in sea gas transport capacity and the construction of new gas transport pipelines are expected.

As indicated by Fujitani et al. [2], while pipelines on land and in the sea can deliver the gas in gaseous form only over relatively short distances, another means of transporting the gas in larger quantities over longer distances is required.

The most cost efficient way of transporting gas between continents is to carry it in liquid form using ships. Further transport cost reductions can be achieved by decreasing the weight of the ship using composite materials rather than steel, since composites have a higher weight-to-stiffness ratio.

The aim of this study is to investigate the suitability of sandwich composite shells as structural members of cylindrical or spherical tanks by analysing stress distribution through the shell thickness and the shell deformations under pressure loading.

1 PRESSURIZED LIQUEFIED GAS TANKS

Liquefied gasses are defined as consisting of a broad range of petroleum gas mixtures, which, as listed in the rules of Turkish Lloyd [3], include: acetaldehyde, ammonia, butane, carbon dioxide, ethane, ethylene, nitrogen, refrigerant gasses, sulphur dioxide, etc.

Liquefied gas transportation distinguishes three major gas conditions: (i) fully pressurized (pressurized at ambient temperature), (ii) semi-refrigerated (pressurized and refrigerated at optimum temperature and pressure), (iii) fully refrigerated (refrigerated at or near atmospheric pressure). The loads associated with these liquefied gas conditions are one of the main characteristics that determine the pressurized tank design. For refrigerated tanks, the tank material’s low-temperature toughness becomes the most important property to consider, since most materials become...
brittle below a certain temperature. Some liquefied
gasses, such as ammonia, butane, propane, propylene
and vinyl chloride, can be transported at ambient
temperatures. Although the storage temperature is not
considered for liquefied gasses, operating temperature
causd by environmental conditions shall be taken
into account in terms of stationary thermal loads. The
operating temperature may give rise to significant
thermal stresses. Therefore, each cargo tank is fitted
with at least one liquid level gauging device, designed
to operate at pressures not less than the maximum
allowable relief valve setting at the temperatures
within the cargo operating temperature range [3].

These liquefied gasses are transported via
cylindrical or spherical cargo tanks at a vapour
pressure of maximum 18 MPa, as indicated by Fujitani
et al. [2]. In this study, the main loading is considered
to be the maximum vapour pressure, ignoring
thermal stresses caused by operating temperature and
environmental conditions.

In addition to the liquefied gas storage
temperature, tank design is also done according to
the cargo tank arrangement restrictions from the
International Code for the construction and equipment
of ship carrying liquefied gasses in bulk (ICG code),
incorporated into the Safety of life at sea (SOLAS)
convention. According to the ICG code, liquefied
gasses that do not need to be refrigerated, are restricted
to Type C tanks, which are structurally independent
of the ship’s hull. Fig. 1 shows a generic mid-ship
section view of a hull and cargo tank.

Type C cargo tanks are completely self-
supporting and do not form part of the ship’s hull,
and do not contribute to the hull strength [2]. Similar
applications of independent tanks are also common
at liquefied natural gas (LNG) ships, as presented in
Fig. 2. However LNG tanks, which store the gas at
-162 °C, are not investigated in this study, because the
refrigeration temperature effect on the tank material
is beyond the scope of this study. Nevertheless, since

LNG tanks are cylindrical and spherical in shape, the
present methodology also could be applied to these
tanks.

![Image of hull-independent tank](image_url)

**Fig. 2. Hull-independent tank on an LNG carrier [4]**

2 COMPOSITE MATERIALS

As presented by Mouritz et al. [5], composite
materials can be chosen for several functional
components of ships, such as hull (complete or partial
as for bulkheads), superstructure (complete for small
crafts, or partial for bigger crafts), for the mast, for
the propulsion system components, and even for
propellers.

One major reason for these choices is the
composites’ high stiffness-to-weight ratio, which
reduces the components weight; another reason is the
lower cost of moulding complex geometry parts rather
than machining them.

Moreover, the design flexibility inherent in
composite laminates, which is described as tailoring
by Kabir et al. [6], makes composites a reasonable
choice for obtaining optimum specific design
requirements through a combination of structural/material concepts, stacking sequence, ply orientation,
choice of the component phases, etc. These allow
composites to provide modern solutions for thermal
and acoustic insulation, stealth capabilities, shock
resistance, etc.

When Liquefied Petroleum Gas (LPG) is in a
hull-independent type C tank, no thermal insulation
is required. Therefore, the design of the material can
be tailored to be non-flammable and to bear the load
while minimizing weight.

Utilization of composite materials, however, also
brings difficulties to the analyst, such as the inter-
laminar or transverse shear stress due to mismatch
of material properties among layers, bending-
stretching coupling due to lamination asymmetry,
and in-plane orthotropy. The transverse stress and
strain components are ignored in classical or thin
shell theories, which makes these theories inadequate
for the analysis of thicker shells. Hence, reliable prediction of deformations and stresses for thicker structures require the use of higher order shear deformation theories, which are based on a cubic or higher expansion of the in-plane displacements. Higher order theories introduce additional unknowns that are difficult to interpret in physical terms and require more mathematical computations for finding solutions [7] and [8].

As indicated by Youssif [9], to analyse the effects of design sensitivities efficiently and accurately, it is crucial to have the appropriate techniques associated with good structural models. Therefore, it is essential to develop a solution methodology considering the additional complexities arising by way of satisfying boundary conditions that cannot be handled by Navier’s or Levy’s traditional analytical approaches. Chaudhuri [10] provides the mathematical explanations for the boundary discontinuous type Fourier series approach for solving completely coupled system of partial differential equations, subjected to admissible general boundary conditions.

In this particular study, static deflections of cylindrical and spherical shaped pressurized tanks made of sandwich composites are investigated by using the higher order shear deformation theory. The effects of boundary conditions on the solution functions are introduced as described by Oktem and Chaudhuri [11] and the presented solution methodology is developed to apply to sandwich composites.

3 DEFINITION OF THE PROBLEM

The geometry of a composite shell, which consists of laminated plies with uniform thicknesses is shown in Fig. 3, where a and b represent the dimensions in the \( \xi_1, \xi_2 \) axes respectively, while \( \xi_3 \) is a line normal to the mid-surface defined at the centre going through the shell thickness \( h \). The terms \( R_1 \) and \( R_2 \) are the mid-surface curvatures in the \( (\xi_1, \xi_2) \) axes respectively.

![Fig. 3. Rectangular panel geometry of a composite shell](image)

The displacement field by considering the cubic terms and satisfying the conditions of transverse shear stresses (and hence strains) vanishing at a point \((\xi_1, \xi_2, \pm h/2)\) on the top and bottom surfaces of the shell, is given by Reddy [12] as follows:

\[
\begin{align*}
\mathbf{u}_1 &= u(\xi_1, \xi_2, \xi_3) = u_0(\xi_1, \xi_2) + \\
&+ z\varphi_1(\xi_1, \xi_2, \xi_3) - \frac{4}{3h^2}z^3\left[\varphi_2 + \frac{\partial w_0}{\partial \xi_1}\right], \quad (1a) \\
\mathbf{u}_2 &= v(\xi_1, \xi_2, \xi_3) = v_0(\xi_1, \xi_2) + \\
&+ z\varphi_2(\xi_1, \xi_2, \xi_3) - \frac{4}{3h^2}z^3\left[\varphi_1 + \frac{\partial w_0}{\partial \xi_2}\right], \quad (1b) \\
\mathbf{u}_3 &= w(\xi_1, \xi_2, \xi_3) = w_0(\xi_1, \xi_2), \quad (1c)
\end{align*}
\]

where \( u, v, w \) represent displacements of a point at three axes \( \xi_1, \xi_2, \xi_3 \), while \( u_0, v_0, w_0 \) are displacements of a point at the mid-surface \( (\xi_3 = 0) \).

Equilibrium equations derived by using the principles of virtual work are given as follows [12]:

\[
\begin{align*}
\frac{\partial N_1}{\partial \xi_1} + \frac{\partial N_2}{\partial \xi_2} &= 0, \quad (2a) \\
\frac{\partial N_1}{\partial \xi_1} + \frac{\partial N_2}{\partial \xi_2} &= 0. \quad (2b)
\end{align*}
\]
\[
\frac{\partial Q_1}{\partial \xi_1} + \frac{\partial Q_2}{\partial \xi_2} - 4 \left( \frac{\partial K_1}{\partial \xi_1} + \frac{\partial K_2}{\partial \xi_2} \right) + \\
+ \frac{4}{3} \left( \frac{\partial^2 P_1}{\partial \xi_1^2} + \frac{\partial^2 P_2}{\partial \xi_2^2} + 2 \frac{\partial^2 P_3}{\partial \xi_1 \partial \xi_2} \right) = -Q, \tag{2c}
\]

\[
\frac{\partial M_{i1}}{\partial \xi_1} + \frac{\partial M_{i2}}{\partial \xi_2} - Q = 4 \frac{\partial}{\partial \xi_i} \left( \frac{\partial P_1}{\partial \xi_1} + \frac{\partial P_2}{\partial \xi_2} \right) = 0, \tag{2d}
\]

\[
\frac{\partial M_{i3}}{\partial \xi_3} + \frac{\partial M_{i4}}{\partial \xi_4} - Q = 4 \frac{\partial}{\partial \xi_i} \left( \frac{\partial P_3}{\partial \xi_1} + \frac{\partial P_4}{\partial \xi_2} \right) = 0. \tag{2e}
\]

In Eq. (2), \( q \) is the transverse load and \( N_i, M_i, P_i, \ i = 1, 2, 6 \) denotes stress resultants, stress couples and second stress couples (see, e.g., Reddy [12]). \( Q_i \) (\( i = 1, 2 \)) represents the transverse shear stress resultants. They are given as follows:

\[
N_i = A_{ij} e_j^0 + B_{ij} \kappa_j^0 + E_{ij} \kappa_j^2, \quad (i, j = 1, 2, 6), \tag{3a}
\]

\[
M_i = B_{ij} e_j^0 + D_{ij} \kappa_j^0 + F_{ij} \kappa_j^2, \tag{3b}
\]

\[
P_i = E_{ij} e_j^0 + F_{ij} \kappa_j^0 + H_{ij} \kappa_j^2, \tag{3c}
\]

\[
Q_i = A_{ij} e_j^0 + D_{ij} \kappa_j^0, \quad (j = 4, 5), \tag{3d}
\]

\[
Q_5 = A_{ij} e_j^0 + F_{ij} \kappa_j^0, \tag{3e}
\]

\[
K_i = D_{ij} e_j^0 + F_{ij} \kappa_j^0, \quad (i = 6, 4), \tag{4d}
\]

in which \( A_{ij}, B_{ij}, \) etc. are the laminate rigidities (integrated stiffnesses). These are given as follows:

\[
(A_{ij}, B_{ij}, D_{ij}) = \sum_{k=1}^{N} \int_{\xi_k}^{\xi_{k+1}} Q^{(k)}(1, z^2) dz, \tag{5a}
\]

\[
(E_{ij}, F_{ij}, H_{ij}) = \sum_{k=1}^{N} \int_{\xi_k}^{\xi_{k+1}} Q^{(k)}(z^1, z^4, z^8) dz. \tag{5b}
\]

Generalized stress-strain constitutive relations for an orthogonal lamina can be expressed as follows:

\[
\begin{bmatrix}
\sigma_1 \\
\sigma_2 \\
\sigma_6 \\
\sigma_5 \\
\sigma_4
\end{bmatrix} =
\begin{bmatrix}
Q_{11} & Q_{12} & 0 & 0 & 0 \\
Q_{12} & Q_{22} & 0 & 0 & 0 \\
0 & 0 & Q_{66} & 0 & 0 \\
0 & 0 & 0 & Q_{55} & 0 \\
0 & 0 & 0 & 0 & Q_{44}
\end{bmatrix}
\begin{bmatrix}
\varepsilon_1 \\
\varepsilon_2 \\
\varepsilon_6 \\
\varepsilon_5 \\
\varepsilon_4
\end{bmatrix}, \tag{6a}
\]

expressions in terms of engineering constants are given below:

\[
Q_{11} = \frac{E_i}{1-\nu_i\nu_{21}}, \quad Q_{12} = \frac{\nu_i E_i}{1-\nu_i\nu_{21}}, \tag{6b}
\]

\[
Q_{22} = \frac{E_i}{1-\nu_{12}\nu_{21}}, \quad Q_{66} = G_{12}, \tag{6c}
\]

\[
Q_{44} = G_{23}, \quad Q_{55} = G_{13}. \tag{6d}
\]

The introduction of Eqs. (3) and (4) into Eq. (2) gives five highly coupled fourth-order partial differential equations. The set of equations can be expressed in the following form:

\[
K_{ij} x_j = f_i \quad (i,j = 1, 2, 6) \quad \text{and} \quad (K_{ii} = 0), \tag{7a}
\]

where

\[
\begin{cases}
\begin{aligned}
x_1 &= u_1, \quad x_2 = u_2, \quad x_3 = u_3, \quad x_4 = \phi_1, \quad x_5 = \phi_2, \quad x_6 = \phi_3, \\
f_1 &= (0 \quad 0 \quad -Q_{mn} \quad 0 \quad 0),
\end{aligned}
\end{cases}
\tag{7b}
\]

Definitions of \([K_{ij}]\) elements are given in Appendix A. The load term \(Q_{mn}\) is a uniformly distributed load (the main load definition for pressurized tanks), and is defined as \([11]\):

\[
Q_{mn} = \frac{16q}{\pi^2 mn}. \tag{8}
\]

4 SOLUTION METHODOLOGY

A tank surface composed of cylindrical and spherical shells can simply be considered to be a doubly curved shell. If part of the tank shell, in the form of a rectangular panel, is inspected separately, the orthotropic shell cannot move in the longitudinal or transversal directions. However, rotations on the edges are possible. It is assumed that these constraints ensure that the following boundary conditions are true for all the edges of the selected shell part.

\[
u_i(0, \xi_j) = \nu_i(\xi_j, 0) = \nu_i(\xi_j, b) = 0, \tag{9a}
\]

\[
u_i(0, \xi_j) = \nu_i(\xi_j, 0) = \nu_i(\xi_j, b) = 0, \tag{9b}
\]

\[
u_j(0, \xi_j) = \nu_j(\xi_j, 0) = \nu_j(\xi_j, b) = 0, \tag{9c}
\]

\[
\phi_1(\xi_j, 0) = \phi_1(\xi_j, b) = \phi_1(0, \xi_j) = \phi_1(b, \xi_j) = 0, \tag{9d}
\]

\[
M_2(\xi_j, 0) = M_2(\xi_j, b) = M_1(0, \xi_j) = M_1(b, \xi_j) = 0. \tag{9e}
\]

Using Sandwich Composite Shells for Fully Pressurized Tanks on Liquefied Petroleum Gas Carriers
The particular solution to the boundary-value problem of an HSDT-based cross-ply shell assumes amplitudes \( U_{mn}, V_{mn} \) and \( W_{mn} \) at \( \zeta_1, \zeta_2, \zeta_3 \) axes, respectively and \( X_{mn}, Y_{mn} \) for rotations about \( \zeta_2 \) and \( \zeta_3 \) axes. Solution functions are examined at the shell boundaries through the length \( a \) and width \( b \) of the shell geometry and organized solution functions at the boundaries are settled by equalities [12].

\[
\begin{align*}
\Phi_1 (\xi_1, \xi_2) &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} U_{mn} R_1 (\xi_1, \xi_2), \quad 0 < \xi_1 < a, \quad 0 \leq \xi_2 < b, \quad (10a) \\
\Phi_2 (\xi_1, \xi_2) &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} V_{mn} R_2 (\xi_1, \xi_2), \quad 0 \leq \xi_1 < a, \quad 0 \leq \xi_2 < b, \quad (10b) \\
\Phi_3 (\xi_1, \xi_2) &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} W_{mn} R_3 (\xi_1, \xi_2), \quad 0 < \xi_1 < a, \quad 0 < \xi_2 < b, \quad (10c) \\
\Psi_1 (\xi_1, \xi_2) &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} X_{mn} R_1 (\xi_1, \xi_2), \quad 0 < \xi_1 < a, \quad 0 \leq \xi_2 < b, \quad (10d) \\
\Psi_2 (\xi_1, \xi_2) &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} Y_{mn} R_2 (\xi_1, \xi_2), \quad 0 \leq \xi_1 < a, \quad 0 < \xi_2 < b, \quad (10e) \\
\end{align*}
\]

where,

\[
\begin{align*}
R_1 (\xi_1, \xi_2) &= \cos(\alpha \xi_1) \sin(\beta \xi_2), \quad (11a) \\
R_2 (\xi_1, \xi_2) &= \sin(\alpha \xi_1) \cos(\beta \xi_2), \quad (11b) \\
R_3 (\xi_1, \xi_2) &= \sin(\alpha \xi_1) \sin(\beta \xi_2), \quad (11c) \\
\alpha &= \frac{m \pi}{a}, \quad \beta = \frac{n \pi}{b}. \quad (11d) \\
\end{align*}
\]

The next step is substituting assumed particular solutions (Eq. (10)) into equilibrium Eq. (2). The differentiation procedure for these functions is based on Lebesque integration theory, which introduces boundary Fourier coefficients arising from discontinuities of the particular solutions at the edges. As has been noted by Chaudhuri [10], the boundary Fourier coefficients serve as a complementary solution to the problem under investigation. The partial derivatives, which cannot be obtained by term-wise differentiation, are given by Oktem and Chaudhuri [11], as follows,

\[
\begin{align*}
u_{11} &= \frac{1}{2} \sum_{m=1}^{\infty} c_1 \sin(\beta \xi_2) + \\
&+ \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \left\{-\alpha^2 U_{mn} + \alpha_{mn} + \beta_{mn} \right\} \sin(\alpha \xi_1) \cos(\beta \xi_2), \quad (13)
\end{align*}
\]

The boundary Fourier coefficients \( \alpha_{mn}, \beta_{mn} \) etc., which appear in Eqs. (8) to (12), are defined in Appendix B. The remaining partial derivatives can be obtained by term-wise differentiation.

The resulting equations are supplied by the geometric and natural boundary conditions, which are presented by Oktem and Chaudhuri [11], and are not rewritten here to keep the presentation shorter.

### 5 NUMERICAL RESULTS AND DISCUSSIONS

Numerical results are presented for composites, for which laminates have a cross-ply \([0°/90°]\) arranged carbon fibres impregnated in an epoxy resin prepreg, with the polyurethane foam core material of varying thicknesses. The doubly-curved shell geometry includes cylindrical and spherical tank forms. The applied loading is a pressure with a value of 18 MPa, which is the maximum storage pressure for LPG carriers [2].

For the numerical solutions, commercially available materials are chosen. The following material properties are provided from their producers. Carbon epoxy prepreg is used for face sheets and generic polyurethane foam for core layers.

### Table 1. Material properties of the face sheets and the core

<table>
<thead>
<tr>
<th>Part</th>
<th>Material</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>Face Sheets</td>
<td>Carbon Epoxy (AS4/3501-6 [0°/90°]-s)</td>
<td>( E=68.3 \text{ GPa}, v=0.05 ) (at 121 °C)</td>
</tr>
<tr>
<td>Core</td>
<td>Polyurethane foam</td>
<td>( E=225 \text{ MPa}, G=67.2 \text{ MPa} ) (at 70 °C)</td>
</tr>
</tbody>
</table>
Here $E$ is the in-plane Young’s modulus, and $G$ denotes in-plane shear modulus while $\nu$ is major Poisson’s ratio.

In the calculations, the following normalized quantities are defined:

$$u_3^* = \left(10^3 E h^2 / p_0 a^3\right)u_3,$$  \hspace{1cm} (17a)

$$M_1^* = \left(10^3 / p_0 a^2\right)M_1,$$  \hspace{1cm} (17b)

$$\sigma_1^* = 10\left(h^2 / p_0 b^2\right)\sigma_1,$$  \hspace{1cm} (17c)

in which $a$ and $b$ are the edge length values of the panel, and $p_0$ denotes the transverse load. For the numerical results presented in the tables and figures, the normalized quantities are computed at the centre of the panel.

Varying values of shallowness ratio $R/L$ (radius/length) and thickness ratio $a/h$ (edge-length/thickness) are considered to show the effect of geometry changes. In addition, the effect of the core thickness is investigated by means of stress distribution through the thickness of the shell.

The solution methodology requires the control of convergence in order to define the required number of terms to include in the equations. Fig. 5 shows the convergence of the normalized central transverse displacement $u_3^*$ and the moment $M_1^*$ of a moderately thick $a/h=10$ symmetric cross-ply $[0°/90°]_s$ sandwich shell, having a core thickness $c$ ratio $a/c=10$ under a pressure loading of 18 MPa. The normalized displacement $u_3^*$ and moment $M_1^*$ exhibit a fast convergence. Nonetheless, the selected number of terms to be used in the numerical analyses is $n=m=40$.

![Fig. 5. Convergence of the normalized central deflection $u_3^*$ and moment $M_1^*$ for a symmetric moderately thick cross-ply $[0°/90°]_s$ sandwich shell](image)

The obtained results are compared to the results of the counterpart analyses using the first order shear deformation theory (FSDT) and the finite element analyses (FEA). The computer program used for validation purposes is the commercially available FEA software ANSYS. Shell geometry is modeled with $R/L=10$ shallowness at both radii $R_1$ and $R_2$, and with the ANSYS shell 91 element type with the sandwich option activated. Uniformly distributed loading is applied as pressure loading over the shell surface. The FEA layered shell model is presented in Fig. 6.

![Fig. 6. Layered element model for a $0°/90°/core/90°/0°$ laminate](image)

The results of the present theory are in concordance with FEA and FSDT counterparts, as can be seen in Fig. 7, which compares varying $a/h$ ratios by means of the normalized deflection $u_3^*$ at the centre of the shell for the core material thickness ratio $a/c$ of 10 and 100.

![Fig. 7. Results from the present theory compared to the FEA and FSDT counterparts for varying $a/h$ ratios by means of the normalized deflection $u_3^*$ at the centre of the shell](image)

The effect of changing the panel dimensions is investigated by analysing the deflection and moment values at the centre of the shell. The results are presented in Fig. 8 according to varying ratios of edge lengths $a/b$ where increasing in this ratio causes the panel to become a beam. Major differences arise as a result of the effect of core material addition that was analyzed through central normalized deflections. Therefore, sandwich shells are suitable not only because they are stiff, but also because they can be...
tailored to additional requirements, such as thermal insulation or fire retardancy of the core material.

The effect of varying the laminates thickness (Fig. 9) and the core material thickness (Fig. 10) ratios are investigated by analysing the doubly-curved shell centre normalized deflections.

The tank geometry curvature, in the vertical and horizontal inclination, is described by the shallowness ratio $R/L$. Referring to this ratio, the doubly curved panel has two radii $R_1$ and $R_2$, as presented in Fig. 3. In the case of a spherical tank, the radii are made equal $R_1 = R_2$, while a cylindrical tank is obtained by letting $R_1 \to \infty$ or $R_2 \to \infty$.

Setting both radii equal to infinity a flat plate is obtained. The effect of the shallowness ratio is presented in Fig. 11, which showing the normalized central deformations at varying $R_1/L$ values for spherical and cylindrical shells.

Fig. 12 shows the inter-laminar normalized stress values for different core thicknesses; for a moderately thick $a/h = 10$ symmetric $[0°/90°/\text{core}/90°/0°]$ shell $R/L = 10$. While normalized stress reaches its maximum value at the top and bottom surfaces, the effect of the core material thickness is observed at the mid-surface of the shell.

An analytical solution to the problem of deformation of a finite-dimensional, cross-ply, thick, doubly curved sandwich shell is applied to fully pressurized composite LPG tanks. The mathematical model of the problem is solved using the boundary discontinuous generalized double Fourier series approach, and the results are in accordance with FSDT and FEA counterparts. Therefore, the presented analytical
method provides a benchmark solution for cylindrical and spherical fully pressurized composite LPG tanks. Further results are concluded as follows:

- The predictive assessment of the developed solution methodology is shown by comparing the numerical application results of the FSDT and FEA solutions.
- Although FEA is widely used by various researchers, the present methodology, developed for cylindrical and spherical sandwich shells may be preferred due to its lower computational demand.
- The effect of core layer thickness on the normalized central deflection of the shell is remarkable. Therefore, core layer thickness, as one of the major parameters, can be used for varying LPG tank geometries.
- The effect of geometry, as another main parameter for tank design, has major effects on deflection values. Moreover, the curvature of the shell results in moderate changes on a central deflection.
- The effect of core layer thickness over the inter-laminar stress distribution is also impressive. Increased thicknesses result in a notable decrease on inter-laminar stress distribution.

7 ACKNOWLEDGEMENT

CAD model of LNG carrier that is used in the article for demonstration purposes (Fig.2) is provided by SEFT Ship Design, a leading company on maritime and naval design programs in Turkey. The author would like to express a deep sense of appreciation and gratitude to General Manager Mr Semih Zorlu for his kind cooperation and help.

\[ \text{where;} \]
\[ \left( A_{ij}, B_{ij}, D_{ij} \right) \right) = \sum_{n=-N}^{N} Q_n^j(z, z^2) \, dz, \quad (A15) \]
\[ \left( E_{ij}, F_{ij}, H_{ij} \right) \right) = \sum_{n=-N}^{N} Q_n^j(z, z^2) \, dz, \quad (A16) \]
\[ c_i = -\frac{4}{3h^2}, \quad (A17) \]

10 APPENDIX B

Definition of boundary Fourier coefficients
\[ \tilde{a}_{ij} = \frac{4}{ab} \int_0^a \left[ u_i (a, \xi) - u_i (0, \xi) \right] \cos (\beta \xi) \, d\xi, \quad (B1) \]
\[ \tilde{b}_{ij} = -\frac{4}{ab} \int_0^a \left[ u_i (a, \xi) - u_i (0, \xi) \right] \sin (\beta \xi) \, d\xi, \quad (B2) \]
\[ \tilde{c}_{ij} = \frac{4}{ab} \int_0^a \left[ u_{ij} (\xi, b) - u_{ij} (\xi, 0) \right] \sin (\alpha \xi) \, d\xi, \quad (B3) \]
\[ \tilde{d}_{ij} = -\frac{4}{ab} \int_0^a \left[ u_{ij} (\xi, b) + u_{ij} (\xi, 0) \right] \sin (\alpha \xi) \, d\xi. \quad (B4) \]
